# PLSC 504: Fall 2022 Panel Data for Non-Continuous Responses (including GEEs)

October 17, 2022

One-way unit effects:

$$Y_{it} = f(\mathbf{X}_{it}\beta + \alpha_i + u_{it})$$

for logit only, so:

$$\Pr(Y_{it} = 1) = \frac{\exp(\mathbf{X}_{it}\beta + \alpha_i)}{1 + \exp(\mathbf{X}_{it}\beta + \alpha_i)} \equiv \Lambda(\mathbf{X}_{it}\beta + \alpha_i)$$

#### Incidental Parameters:

- Nonlinearity  $\rightarrow$  inconsistency in both  $\hat{\alpha}$ s and  $\hat{\beta}$ .
- Anderson:

$$L^{U} = \prod_{i=1}^{N} \prod_{t=1}^{T} \Lambda(\mathbf{X}_{it} + \alpha_i)^{\mathbf{Y}_{it}} [1 - \Lambda(\mathbf{X}_{it} + \alpha_i)]^{1 - \mathbf{Y}_{it}}$$

Chamberlain:

$$L^{C} = \prod_{i=1}^{N} \Pr\left(Y_{i1} = y_{i1}, Y_{i2} = y_{i2}, ... Y_{iT} = y_{iT} \mid \sum_{t=1}^{T} Y_{it}\right)$$

## Fixed-Effects (continued)

Intuition: Suppose we have T=2. That means that:

- $Pr(Y_{i1} = 0 \text{ and } Y_{i2} = 0 \mid \sum_{\tau} Y_{it} = 0) = 1.0$
- $Pr(Y_{i1} = 1 \text{ and } Y_{i2} = 1 \mid \sum_{T} Y_{it} = 2) = 1.0$

and:

$$\Pr\left(Y_{i1} = 0 \text{ and } Y_{i2} = 1 \mid \sum_{\mathcal{T}} Y_{it} = 1\right) = \frac{\Pr(0, 1)}{\Pr(0, 1) + \Pr(1, 0)}$$

with a similar statement for  $Pr(Y_{i1} = 1 \text{ and } Y_{i2} = 0 \mid \sum_{T} Y_{it} = 1)$ .

#### Points:

- Fixed effects = no estimates for  $\beta_b$
- Interpretation: per logit, but  $|\hat{\alpha}_i|$ .
- BTSCS in IR: Green et al. (2001) v. B&K (2001).

Model is:

$$Y_{it}^* = \mathbf{X}_{it}\beta + u_{it}$$
  
 $Y_{it} = 0 \text{ if } Y_{it}^* \le 0 ;$   
 $= 1 \text{ if } Y_{it}^* > 0$ 

with:

$$u_{it} = \alpha_i + \eta_{it}$$

with  $\eta_{it} \sim \text{i.i.d. N(0,1)}$ , and  $\alpha_i \sim N(0, \sigma_{\alpha}^2)$ . This implies:

$$Var(u_{it}) = 1 + \sigma_{\alpha}^2$$

and so:

$$\mathsf{Corr}(u_{it}, u_{is}, \ t \neq s) \equiv \rho = \frac{\sigma_{\alpha}^2}{1 + \sigma_{\alpha}^2}$$

which means that we can write  $\sigma_{\alpha}^2 = \left(\frac{\rho}{1-\rho}\right)$ .

#### Random Effects Variants

Probit:

$$L_{i} = \text{Prob}(Y_{i1} = y_{i1}, Y_{i2} = y_{i2}, ... Y_{iT} = y_{iT})$$

$$= \int_{-\infty}^{X_{i1}\beta} \int_{-\infty}^{X_{i2}\beta} ... \int_{-\infty}^{X_{iT}\beta} \phi(u_{i1}, u_{i2}...u_{iT}) du_{iT}... du_{i2} du_{i1}$$

Logit:

$$L_{i} = \operatorname{Prob}(Y_{i1} = y_{i1}, Y_{i2} = y_{i2}, ... Y_{iT} = y_{iT})$$

$$= \int_{-\infty}^{X_{i1}\beta} \int_{-\infty}^{X_{i2}\beta} ... \int_{-\infty}^{X_{iT}\beta} \lambda(u_{i1}, u_{i2}...u_{iT}) du_{iT}... du_{i2} du_{i1}$$

Solution?

$$\phi(u_{i1}, u_{i2}, ... u_{iT}) = \int_{-\infty}^{\infty} \phi(u_{i1}, u_{i2}, ... u_{iT} \mid \alpha_i) \phi(\alpha_i) d\alpha_i$$

## Practical Things

- $\hat{\rho}$  = proportion of the variance due to the  $\alpha_i$ s.
- Implementation: Gauss-Hermite guadrature or MCMC.
- Best with N large and T small.
- Critically requires  $Cov(\mathbf{X}, \alpha) = 0$  (see notes re: Chamberlain's CRE Estimator).

## Unit Effects in Practice - Some Simulations

Start with:

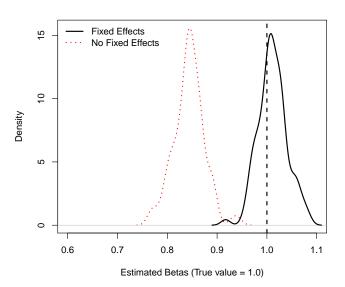

$$Y_{it}^* = 0 + (1 \times X_{it}) + (1 \times D_{it}) + (1 \times \alpha_i) + u_{it}$$
  
 $Y_{it} \in \{0,1\} = f(Y_{it}^*)$ 

#### where:

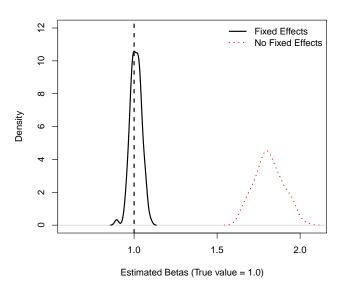

- $\alpha_i \sim N(0,1)$
- $X_{it} \sim N(0, \sigma_X^2)$
- $D_{it} \in \{0, 1\}$
- $Cov(X_{it}, \alpha_i) = \{0, 0.69\}$
- $Cov(D_{it}, \alpha_i) = 0$
- $f(\cdot) = \{ \text{logit, probit} \}$  (as appropriate)

and N = T = 100.

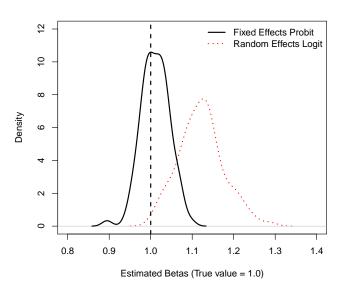

# Logit $\hat{\beta}_X$ s for $Cov(X_{it}, \alpha_i) = 0$

# Logit $\hat{\beta}_X$ s for $Cov(X_{it}, \alpha_i) \approx 0.69$

# Logit $\hat{\beta}_X$ s for $Cov(X_{it}, \alpha_i) \approx 0.69$

#### Software

#### R

- pglm (panel GLMs) (maximum likelihood + quadrature)
- bife (fixed-effects logit / probit only)
- glmer (general mixed-effects models, including RE)
- glmmML (via Gauss-Hermite quadrature)
- MCMCpack (MCMChlogit)
- Various user-generated functions (e.g., here).

#### Stata

- xtprobit, xtlogit, xtcloglog
- Plus xttrans (transition probabilities), quadchk (quadrature checking), xtrho / xtrhoi (estimation of within-unit covariances)

## Example: WDI "Plus"

#### Data from the WDI plus POLITY and the UCDP:

- ISO3 The country's International Standards Organization (ISO) three-letter identification code.
- Year The year that row of data applies to.
- CivilWar Civil conflict indicator: 1 if there was a civil conflict in that country in that year;
   0 otherwise. From UCDP.
- OnsetCount The sum of new conflict episodes in that country / year. From UCDP.
- LandArea Land area (sq. km).
- PopMillions Popluation (in millions).
- PopGrowth Population Growth (percent).
- UrbanPopulation Urban Population (percent of total).
- GDPPerCapita GDP per capita (constant 2010 \$US).
- GDPPerCapGrowth GDP Per Capita Growth (percent annual).
- PostColdWar 1 if Year > 1989, 0 otherwise.
- POLITY The POLITY score of democracy/autocracy. Scaled so that 0 = most autocratic, 10 = most democratic.

 $N=216, \ \bar{T}=61, \ NT \ \text{varies (due to missingness)}.$

#### **Event Counts: Unit Effects**

$$Y_{it} \sim \mathsf{Poisson}(\mu_{it} = \alpha_i \lambda_{it})$$

with  $\lambda_{it} = \exp(\mathbf{X}_{it}\boldsymbol{\beta})$  implies:

$$E(Y_{it} \mid \mathbf{X}_{it}, \alpha_i) = \mu_{it}$$

$$= \alpha_i \exp(\mathbf{X}_{it}\beta)$$

$$= \exp(\delta_i + \mathbf{X}_{it}\beta)$$

where  $\delta_i = \ln(\alpha_i)$ .

#### Fixed-Effects Poisson:

- ...has no "incidental parameters" problem (see e.g. Cameron and Trivedi, pp. 281-2)
- This means "brute force" approach works
- Fitted via glmmML in R, xtpoisson (and xtnbreg) in Stata

#### Random-Effects Models

$$\Pr(Y_{i1} = y_{i1}, ... Y_{iT} = y_{iT}) = \int_0^\infty \Pr(Y_{i1} = y_{i1}, ... Y_{iT} = y_{iT}) f(\alpha_i) d\alpha_i$$
$$= \int_0^\infty \left[ \prod_{t=1}^T \Pr(Y_{it} \mid \alpha_i) \right] f(\alpha_i) d\alpha_i$$

- Simplest to assume  $\alpha_i \sim \Gamma(\theta)$
- Yields a model with  $\mathsf{E}(Y_{it}) = \lambda_{it}$  and  $\mathsf{Var}(Y_{it}) = \lambda_{it} + \frac{\lambda_{it}^2}{\theta}$
- Via glmmML or glmer in R, or xtpois, re in Stata
- ∃ random effects negative binomial too...

#### Panel Models: Software

#### R:

- Tobit = censReg (in censReg)
- Poisson (random effects) = glmmML in glmmML or glmer in Ime4
- Poisson (fixed effects) = glmmML or "brute force"
- All of the above = pglm

#### Stata:

- Tobit = xttobit (re only)
- Poisson / negative binomial = xtpoisson, xtnbreg (both with fe, re options)

#### Conflict Onsets: Pooled Poisson

## Wrap-Up: Some Useful Packages

#### • pglm

- Workhorse package for panel (FE, RE, BE) GLMs
- Binary + ordered logit/probit, Poisson / negative binomial
- Discussed + used extensively in Croissant and Millo (2018) Panel Data Econometrics with R
- The one thing it won't (apparently) do is fixed-effects, binary-response models...

#### • fixest

- Fast / efficient fitting of FE models
- · Fits linear models, logit, Poisson, and negative binomial
- Includes easy coefficient plots & tables; simple multi-threading; built-in "robust" S.E.s

#### alpaca

- Fast / efficient fitting of GLMs with high-dimensional fixed effects
- Includes bias correction for incidental parameters after binary-response models
- Also includes useful panel data simulation routines + average partial effects

# **GEEs**

## Quick GLM review

Linear-normal model is:

$$Y_i = \mu_i + u_i$$

with:

$$\mu_i = \mathbf{X}_i \boldsymbol{\beta}.$$

Generalize:

$$g(\mu_i) = \mathbf{X}_i \boldsymbol{\beta}$$

and:

$$Y_i \sim \text{i.i.d. } F[\mu_i, \mathbf{V}_i].$$

#### **GLM** Estimation

"Score" equations:

$$\mathbf{U}(\beta) = \sum_{i=1}^{N} \mathbf{D}'_{i} \mathbf{V}_{i}^{-1} [Y_{i} - \mu_{i}] = \mathbf{0}.$$

with:

- $\mathbf{D}_i = \frac{\partial \mu_i}{\partial \beta}$ ,
- $\mathbf{V}_i = rac{h(\mu_i)}{\phi}$ , and
- $(Y_i \mu_i) \approx$  a "residual."
- Known as "quasi-likelihood" (e.g. Wedderburn 1974 Biometrika).

Now suppose:

$$Y_{it} = \mu_{it} + u_{it}$$

where

- $i \in \{1, ...N\}$  are i.i.d. "units,"
- $t \in \{1, ... T\}$ , T > 1 are "time points,"
- we want  $g(\mu_{it}) = \mathbf{X}_{it}\boldsymbol{\beta}$ .

**Key issue**: Accounting for (conditional) dependence in *Y* over time.

#### **GEE Basics**

Full joint distributions over T are hard. But...

Define:

$$\mathbf{R}_{i}(\boldsymbol{\alpha}) = \begin{pmatrix} 1.0 & \alpha_{12} & \cdots & \alpha_{1,T} \\ \alpha_{21} & 1.0 & \cdots & \alpha_{2,T} \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_{T,1} & \cdots & \alpha_{T,T-1} & 1.0 \end{pmatrix},$$

- $\rightarrow$  "working correlation" matrix.
  - Completely defined by  $\alpha$ ,
  - Structure specified by the analyst.

## **GEE Origins**

Liang and Zeger (1986): We can decompose the variance of  $Y_{it}$  as:

$$\mathbf{V}_i = \mathsf{diag}(\mathbf{V}_i^{rac{1}{2}})\,\mathbf{R}_i(lpha)\,\mathsf{diag}(\mathbf{V}_i^{rac{1}{2}})$$

With a standard GLM assumption about the mean and variance, this is:

$$\mathbf{V}_{i} = \frac{\left(\mathbf{A}_{i}^{\frac{1}{2}}\right) \mathbf{R}_{i}(\alpha) \left(\mathbf{A}_{i}^{\frac{1}{2}}\right)}{\phi}$$

where

$$\mathbf{A}_i = egin{pmatrix} h(\mu_{i1}) & 0 & \cdots & 0 \ 0 & h(\mu_{i2}) & \cdots & 0 \ dots & dots & \ddots & dots \ 0 & \cdots & 0 & h(\mu_{iT}) \end{pmatrix}$$

#### What does that mean?

$$V_i = Var(Y_{it}|X_{it}, \beta)$$
 has two parts:

- $\mathbf{A}_i = unit$ -level variation,
- $R_i(\alpha)$  = within-unit *temporal* variation.

## Specifying $\mathbf{R}_i(\alpha)$

Independent: 
$$\mathbf{R}_i(\alpha) = \begin{pmatrix} 1.0 & 0 & \cdots & 0 \\ 0 & 1.0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & 1.0 \end{pmatrix}$$

- Assumes no within-unit temporal correlation.
- Equivalent to GLM on pooled data.

Exchangeable: 
$$\mathbf{R}_{i}(\alpha) = \begin{pmatrix} 1.0 & \alpha & \cdots & \alpha \\ \alpha & 1.0 & \cdots & \alpha \\ \vdots & \vdots & \ddots & \vdots \\ \alpha & \cdots & \alpha & 1.0 \end{pmatrix}$$

- One free parameter in  $\mathbf{R}_i(\alpha)$   $(\alpha_{ts} = \alpha \ \forall \ t \neq s)$
- Temporal correlation within units is constant across time points.
- Akin (in some respects) to a random-effects model...

## Specifying $\mathbf{R}_i(\alpha)$

$$AR(p) \text{ (e.g., } AR(1)): \qquad \mathbf{R}_{i}(\alpha) = \begin{pmatrix} 1.0 & \alpha & \alpha^{2} & \cdots & \alpha^{T-1} \\ \alpha & 1.0 & \alpha & \cdots & \alpha^{T-2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \alpha^{T-1} & \cdots & \alpha^{2} & \alpha & 1.0 \end{pmatrix}$$

- One free parameter in  $\mathbf{R}_i(\alpha)$  ( $\alpha_{ts} = \alpha^{|t-s|} \ \forall \ t \neq s$ ).
- Conditional within-unit correlation an exponential function of the lag.

$$Stationary(p): \qquad \mathbf{R}_i(\alpha) = \begin{pmatrix} 1.0 & \alpha_1 & \cdots & \alpha_p & 0 & \cdots & 0 \\ \alpha_1 & 1.0 & \alpha_1 & \cdots & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & \alpha_p & \cdots & \alpha_1 & 1.0 \end{pmatrix}$$

- AKA "banded," or "p-dependent."
- $p \leq T 1$  free parameters in  $\mathbf{R}_i(\alpha)$ .
- Conditional within-unit correlation an exponential function of the lag, up to lag p, and zero thereafter.

# Specifying $\mathbf{R}_i(\alpha)$

Unstructured: 
$$\mathbf{R}_{i}(\alpha) = \begin{pmatrix} 1.0 & \alpha_{12} & \alpha_{13} & \cdots & \alpha_{1,\tau-1} \\ \alpha_{12} & 1.0 & \alpha_{23} & \cdots & \alpha_{2,\tau-1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \alpha_{1,\tau-1} & \alpha_{2,\tau-1} & \cdots & \alpha_{\tau-1,\tau-1} & 1.0 \end{pmatrix}$$

- $\frac{T(T-1)}{2}$  free parameters in  $\mathbf{R}_i(\alpha)$ .
- Conditional within-unit correlation is completely data-dependent.

Score equations:

$$\boldsymbol{U}_{GEE}(\beta_{GEE}) = \sum_{i=1}^{N} \mathbf{D}_{i}^{\prime} \left[ \frac{(\mathbf{A}_{i}^{\frac{1}{2}}) \, \mathbf{R}_{i}(\alpha) \, (\mathbf{A}_{i}^{\frac{1}{2}})}{\phi} \right]^{-1} \left[ Y_{i} - \mu_{i} \right] = \mathbf{0}$$

#### Two-step estimation:

- For fixed values of  $\alpha_s$  and  $\phi_s$  at iteration s, use Newton scoring to estimate  $\hat{\beta}_s$ ,
- Use  $\hat{\beta}_s$  to calculate standardized residuals  $(Y_i \hat{\mu}_i)_s$ , from which consistent estimates of  $\alpha_{s+1}$  and  $\phi_{s+1}$  can be estimated.

#### Inference

Liang & Zeger (1986):

$$\hat{oldsymbol{eta}}_{ extit{GEE}} \ \mathop{\sim}\limits_{ extit{N} o \infty} \ extbf{N}(oldsymbol{eta}, oldsymbol{\Sigma}).$$

For  $\hat{\Sigma}$ , two options:

$$\hat{\mathbf{\Sigma}}_{\mathsf{Model}} = N \left( \sum_{i=1}^{N} \hat{\mathbf{\mathcal{D}}}_{i}' \hat{\mathbf{\mathcal{V}}}_{i}^{-1} \hat{\mathbf{\mathcal{D}}}_{i} \right)$$

$$\hat{\boldsymbol{\Sigma}}_{\mathsf{Robust}} = N \left( \sum_{i=1}^{N} \hat{\boldsymbol{D}}_{i}^{\prime} \hat{\boldsymbol{V}}_{i}^{-1} \hat{\boldsymbol{D}}_{i} \right)^{-1} \left( \sum_{i=1}^{N} \hat{\boldsymbol{D}}_{i}^{\prime} \hat{\boldsymbol{V}}_{i}^{-1} \hat{\boldsymbol{S}}_{i} \hat{\boldsymbol{V}}_{i}^{-1} \hat{\boldsymbol{D}}_{i} \right) \left( \sum_{i=1}^{N} \hat{\boldsymbol{D}}_{i}^{\prime} \hat{\boldsymbol{V}}_{i}^{-1} \hat{\boldsymbol{D}}_{i} \right)^{-1}$$

where  $\hat{\boldsymbol{S}}_i = (Y_i - \hat{\mu}_i)(Y_i - \hat{\mu}_i)'$ .

# Inference (aka, magic!)

- $\bullet$   $\hat{\Sigma}_{\mathsf{Model}}$ 
  - Requires that  $\mathbf{R}_i(\alpha)$  be "correct" for consistency.
  - Is slightly more efficient than  $\hat{\Sigma}_{\mathsf{Robust}}$  if so.

- ullet  $\hat{\Sigma}_{\mathsf{Robust}}$ 
  - Is consistent even if  $R_i(\alpha)$  is misspecified.
  - Is slightly less efficient than  $\hat{\Sigma}_{\mathsf{Model}}$  if  $\mathsf{R}_i(lpha)$  is correct.

### Moral: Use $\hat{\Sigma}_{\mathsf{Robust}}$

### Summary

#### GEEs:

- Are a straightforward variation on GLMs, and so
- Can be applied to a range of data types (continuous, binary, count, proportions, etc.),
- Yield robustly consistent point estimates of  $\beta$ s,
- Account for within-unit correlation in an informed way, but also
- Yield consistent inferences even if that correlation is misspecified.

# Practical Issues: Model Interpretation

- In general, GEEs = GLMs.
- GEEs are marginal models, so:
  - $\hat{\beta}$ s have an interpretation as average / total effects.
  - Estimates / effect sizes generally be smaller than conditional (e.g. fixed/random) effects models.
  - E.g., for logit,  $\hat{\beta}_M \approx \frac{\hat{\beta}_C}{\sqrt{1+0.35\sigma_\eta^2}}$ , where  $\sigma_\eta^2 > 0$  is the variance of the unit effects.

# Practical Issues: Specifying $\mathbf{R}_i(\alpha)$

- Has been called "more art than science."
- Pointers:
  - Choose based on *substance* of the problem.
  - Remember that  $\mathbf{R}_i(\alpha)$  is conditional on  $\mathbf{X}$ ,  $\hat{\boldsymbol{\beta}}$ .
  - Consider unstructured when T is small and N large.
  - Try different ones, and compare.
- In general, it shouldn't matter terribly much...

# GEEs: Software

Software	Command(s)/Package(s)
R	gee / geepack / geeM / multgeeB / orth / repolr
Stata	<pre>xtgee / xtlogit / xtprobit / xtpois / etc.</pre>
SAS	<pre>genmod (w/ repeated)</pre>

# GEEs: Software Tips

- Generally follow GLMs (specify "family" + "link")
- Certain combinations not possible/recommended
- Estimation: Fisher scoring, MLE, etc. (MCMC?)

From the geepack manual:

#### Warning

Use "unstructured" correlation structure only with great care. (It may cause R to crash).

## Civil War Redux... GEE: Independence

```
